

Linear Search in Java

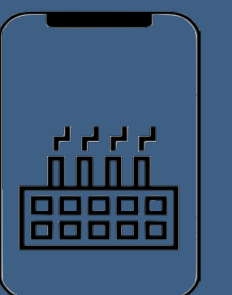

Linear Search Pseudocode

- Create function with two parameters which are an array and a value
- Loop through the array and check if the current array element is equal to the value
- If it is return the index at which the element is found
- If the value is never found return -1

Binary Search in Java

Binary Search Pseudocode

- Create function with two parameters which are a sorted array and a value
- Create two pointers : a left pointer at the start of the array and a right pointer at the end of the array.
- Based on left and right pointers calculate middle pointer
- While middle is not equal to the value and $\text{start} \leq \text{end}$ loop:
 - if the middle is greater than the value move the right pointer down
 - if the middle is less than the value move the left pointer up
- If the value is never found return -1
